ABSTRACT

The peristaltic flow of a copper water fluid investigate the effects of entropy and magnetic field in an endoscope is studied. The mathematical formulation is presented, the resulting equations are solved exactly. The obtained expressions for pressure gradient, pressure rise, temperature, velocity phenomenon entropy generation number and Bejan number are described through graphs for various pertinent parameters. The streamlines are drawn for some physical quantities to discuss the trapping phenomenon.

Keywords: MHD; Peristaltic flow; Copper nanoparticle; Endoscope; Entropy generation.

1. INTRODUCTION

Analysis of peristaltic flow has great practical importance and applications in many biological and biomedical systems. Such systems include the flow of urine through the ureter, the swallowing process through the oesophagus, the movement of spermatozoa in the ductus efferentes of the male reproductive tract, transport of lymph in the lymphatic vessels and in the vasomotion of small blood vessels such as arterioles, venules and capillaries. The literature on peristalsis of viscous fluid is by now quite extensive. Such relevant investigations include the works of Akbar \textit{et al.} (2015), Mekheimer (2002), (2004), Akbar. (2014), Srinivas \textit{et al.} (2009), Ebaid (2008 a, b), Akbar and Nadeem (2012), Misery \textit{et al.} (2003) and Hakeem \textit{et al.} (2002) talked about the effects of an endoscope on the peristaltic motion involving variable viscosity and generalized Newtonian fluids respectively.

Recently, Mekheimer and Elmaboud (2008) examined the peristaltic flow of couple stress fluid in an endoscope. According to them, the effects of an endoscope on the peristaltic fluid is very important for medical diagnosis, and it has many clinical applications, such as it is a very important tool for determining real reasons responsible for many problems in human organs in which the fluid are transported by peristaltic pumping (e.g., stomach small intestine). The endoscope is also like a catheter which is used in contemporary medical science. Some important studies to the topic were included in (2008, 2011)

The study of the peristaltic transport of a fluid in the presence of an external magnetic field and rotation is of great importance with regard to certain problems involving the movement of conductive physiological fluids, for example, blood and saline water. Pandey and Chaube (2011) investigated an analytical study of the MHD flow of a micropolar fluid through a porous medium induced by sinusoidal peristaltic waves traveling down the channel wall.

Li \textit{et al.}, (1994) have concluded that an impulsive magnetic filed in the combined therapy of patients with stone fragments in the upper urinary tract. It was discovered that the Impulsive Magnetic Field activates the impulsive activity of the uretal smooth muscles in 100% of cases. Mekheimer and Al-Arabi (2002) investigated the non - linear peristaltic transport of MHD flow through a porous medium was studied in non - uniform channels.

It is also observed that heat transfer can be augmented through the improvement in the thermal properties of energy transmission fluids. If small solid particles in the fluid are suspended, then this
might be an innovative way of improving the thermal conductivities of fluids. Nanofluids are estimated to show the conventional heat transfer fluids as comparing with superior heat transfer properties (2003). This idea of suspensions of colloidal particles dubbed as nanofluids was given by Choi (1995), he was at the view that small amounts of metallic or metallic oxide nanoparticles are dispersed into water and other fluids.

In thermodynamics, entropy is a measure of the number of specific ways in which a thermodynamic system may be arranged, often taken to be a measure of disorder, or a measure of progressing towards thermodynamic equilibrium. Non-Newtonian fluid flow in a pipe system with entropy generation is considered by Pakdemirli and Yilbas (2006): According to them entropy number increases with increasing Brinkman number. Souidi et al. (2009) discussed entropy generation rate for a peristaltic pump. Entropy generation due to heat and fluid flow in backward facing step flow with various expansion ratios is studied by Abu-Nada et al. (2006). Further analysis could be seen through Refs. (Koo and Kleinstreuer (2004, 2005), Oztop et al. (2005), Dagtekin et al. (2005, 2007), Oztop and Al-Salem (2012), Ghasemi et al. (2012), Rashad and Razavi (2012), Ramiar et al. (2012)).

Motivated by the above analysis, the purpose of this study is to analyze the effect of peristaltic flow with entropy generation in heat conducting nanofluids in the presence of magnetic field in an endoscope. It is important to note that the analysis could be applied to any nanofluid, a copper-water nanofluid is used as the model in this article. We also consider thermal conductivity model with Brownian motion (Koo and. Kleinstreuer 2004)) for nanofluids, this gain the effects of particle size, particle volume fraction and temperature dependence. The analysis is performed under the well-established long wavelength and low Reynolds number approximations. The exact solution for the stream function, temperature and pressure gradient is given. All the physical features of the problems have been described with the help of graphs.

2. MATHEMATICAL FORMULATION

Here we discussed an incompressible peristaltic flow of copper nano fluid in an endoscope. The flow is generated by sinusoidal wave trains propagating with constant speed c along the walls of the tube. Heat transfer along with Entropy generation phenomena has been taken into account. The inner tube is rigid and maintained at temperature $T_0$ while the outer tube has a sinusoidal wave traveling down its walls and maintained at temperature $T_1$. The geometry of the wall surfaces is defined as

$$R_1 = a_1,$$  \hspace{1cm} (1)

$$R_2 = a_2 + b \sin \left[ \frac{2\pi}{\lambda} (Z - c t) \right].$$  \hspace{1cm} (2)

![Fig. 1. Geometry of the problem.](image)

In the above equations $a_1$ is the radius of the inner tube, $a_2$ is the radius of the outer tube at inlet, $b$ is the wave amplitude, $\lambda$ is the wavelength, $c_1$ he wave speed, and $\tau$ the time. Introducing a wave frame $(\tilde{r},\tilde{z})$ moving with velocity $c_1$ away from the fixed frame $(\bar{R},\bar{Z})$ by the transformations

$$z = \bar{Z} - c_1 \tau, \quad r = \bar{R}, \quad w = \bar{W} - c_1, \quad u = \bar{U}$$  \hspace{1cm} (3)

$$\frac{1}{r} \frac{\partial (ru)}{\partial r} + \frac{\partial w}{\partial z} = 0,$$  \hspace{1cm} (4)

$$\rho_{nf} (\frac{\partial u}{\partial t} + ru \frac{\partial u}{\partial r} + w \frac{\partial u}{\partial z}) = -\frac{\partial P}{\partial r} + \frac{\mu_{nf}}{\rho_{nf}} (\frac{\partial^2 u}{\partial r^2} + \frac{1}{r} \frac{\partial u}{\partial r} + \frac{\partial^2 u}{\partial z^2}) - \sigma B^2 \left( \frac{w}{c_1} + 1 \right),$$  \hspace{1cm} (5)

$$\rho_{nf} (\frac{\partial w}{\partial t} + ru \frac{\partial w}{\partial r} + w^2 \frac{\partial w}{\partial z}) = -\frac{\partial P}{\partial z} + \frac{\mu_{nf}}{\rho_{nf}} (\frac{\partial^2 w}{\partial r^2} + \frac{1}{r} \frac{\partial w}{\partial r} + \frac{\partial^2 w}{\partial z^2}) - \sigma B^2 \left( \frac{w}{c_1} + 1 \right),$$  \hspace{1cm} (6)

$$\frac{\partial^2 T}{\partial t^2} + \frac{\partial T}{\partial z} = \alpha_{nf} \left( \frac{\partial^2 T}{\partial r^2} + \frac{1}{r} \frac{\partial T}{\partial r} + \frac{\partial^2 T}{\partial z^2} \right) + \frac{\mu_{nf}}{\rho_{nf}} \left( \frac{\partial w}{\partial r} + \frac{\partial w}{\partial r} \right)^2,$$  \hspace{1cm} (7)

where $P$ is the pressure the ambient value of temperature denoted by $T_0$, $\bar{w}$ and $\bar{u}$ are the velocity components in the $\tilde{r}$ and $\tilde{z}$ directions, respectively, $\bar{T}$ is the local temperature of the fluid. Further, $\rho_{nf}$ is the effective density, $\mu_{nf}$ is the effective dynamic viscosity, $(\rho c_p)_{nf}$ is the heat capacitance, $\alpha_{nf}$ is the effective thermal diffusivity, which are defined as (see Ref. Koo and Kleinstreuer 2004)

$$\rho_{nf} = (1 - \varphi) \rho_f + \varphi \rho_m,$$

$$(\rho c_p)_{nf} = (1 - \varphi) (\rho c_p)_f + \varphi (\rho c_p)_m,$$

$$(\rho \beta)_{nf} = (1 - \varphi) (\rho \beta)_f + \varphi (\rho \beta)_m.$$  \hspace{1cm} (8)
where subscript \(nf\), \(f\) and \(s\) stand for the nanofluid, base fluid and nanoparticle, respectively and \(\phi\) is the solid volume fraction. The corresponding boundary conditions in the wave frame are

\[
\begin{align*}
-w &= -c_1, \quad T = T_0, \quad \text{at } r = r_1, \\
-w &= -c_1, \quad T = T_1, \quad \text{at } r = r_2 = a_2 + b \sin \left(\frac{2\pi}{\lambda}z\right),
\end{align*}
\]

(9) (10)

The dimensionless parameters used in the problem are defined as follow

\[
R = \frac{R}{a_2}, \quad r = \frac{r}{a_2}, \quad Z = \frac{Z}{\lambda}, \quad z = \frac{z}{\lambda}, \quad W = \frac{W}{c_1}, \quad w = \frac{w}{c_1}, \quad \text{Re} = \frac{\nu \, \rho \, \alpha_2}{\mu_{nf}}, \quad \alpha_{nf} = \frac{\alpha}{(\alpha_f)_{nf}}, \quad \tau = \frac{(\tau_f)_{nf}}{(\tau_f)_{sf}}, \quad M^2 = \frac{\sigma B^2_{nf} a_2^2}{\mu_{nf}}.
\]

(11)

After using the above non-dimensional parameters and transformation in Eq. (2) employing the assumptions of long wavelength (\(\delta \to 0\)), the dimensionless governing equations (without using bars) for nanofluid in the wave frame take the final form as

\[
\begin{align*}
\frac{\partial \tilde{u}}{\partial r} + \frac{u}{r} + \frac{\partial \tilde{v}}{\partial z} &= 0, \\
\frac{\partial \tilde{p}}{\partial r} &= 0, \\
\frac{\partial \tilde{p}}{\partial z} &= A \left( \frac{1}{r} \frac{\partial}{\partial r} \left( \frac{\partial \tilde{v}}{\partial r} \right) \right) - M^2 (w + 1), \\
Kf \left[ \frac{1}{r} \frac{\partial}{\partial r} \left( \frac{\partial \tilde{\theta}}{\partial r} \right) \right] + B_f A \left( \frac{\partial \tilde{v}}{\partial r} \right)^2 &= 0,
\end{align*}
\]

(12) (13) (14) (15)

The non-dimensional boundaries will take the form as

\[
\begin{align*}
w &= -1, \quad \text{at } r = r_1, \\
w &= -1, \quad \text{at } y = r_2 = 1 + a \sin (2\pi z), \\
\theta &= 0 \quad \text{at } r = r_1, \quad \theta = 1 \quad \text{at } r = r_2.
\end{align*}
\]

(16) (17) (18)

Eq. (7) are considered to be independent of the movement of nanoparticles. The Brownian motion is claimed to play an important role in modifying the thermal conductivity and viscosity of nanofluids. Among the existing models that predict the thermal conductivity and viscosity of nanofluids with considering the Brownian motion, the models proposed by Koo and Kleinstreuer (2004, 2005) are utilized in the present study. These models have successfully been used by Ghasemi and Aminossadati (2013) to study the effects of Brownian motion on laminar steady-state natural convection in a right triangular enclosure with localized heating on the vertical side. Note that these models were proposed based on water with copper oxide nanoparticles. Although the extension to other combinations of base liquids and nanoparticles may be justified, the material of the nanoparticles being considered in the present study are limited to copper only. In these models, it is assumed that the thermal conductivity and viscosity of nanofluids consist of two parts. One is referred to as the static part (\(k_s\), \(\mu_s\)) that is evaluated by mixture models, i.e., the Maxwell model for thermal conductivity and the Brinkman model for viscosity, and the other part (\(k_B\), \(\mu_B\)) is attributed to the Brownian motion. The expression for predicting the effective thermal conductivity of nanofluids appears as

\[
k_{nf} = k_f + k_B.
\]

(19)

where \(Kf\) is given by the -

\[
Kf = \frac{k_{nf}}{k_f} = \left( \frac{2k_0 \phi \log_{10} \left( \frac{d_f}{\rho} \right) - \phi + 1}{2k_0 \phi \log_{10} \left( \frac{d_f}{\rho} \right) - \phi + 1} \right)
\]

(20)

and \(k_B\) is expressed as [22]

\[
k_B = 5 \times 10^4 \gamma_1 \phi \rho \mu_0 \sqrt{\frac{K_{env}}{\rho d_s F(T_{env}, \phi)}},
\]

(21)

where \(\kappa \tau\) is the Boltzmann constant and its value is \(\kappa \approx 1.38 \times 10^{-22} J / K\), \(d_s\) is the diameter of nanoparticles by assuming that these nanoparticles have a uniform size and are perfectly spherical, i.e. \(d_s = 30 nm\), \(T_{env}\) is a reference temperature that is chosen as \(T_B\) in the current study, \(\gamma_1\) is a function of the volume fraction \(\phi\) of nanoparticles, which is given by

\[
\gamma_1 = \begin{cases} 0.0137(100\phi)^{-0.8229} & \text{for } \phi < 0.01 \\ 0.0011(100\phi)^{-0.7272} & \text{for } \phi > 0.01 \end{cases}
\]

(22)

and the function \(F(T_{env}, \phi)\) is given by

\[
F(T_{env}, \phi) = (-6.04 \phi + 0.4705)T_{env} + (1722.3 \phi - 134.63),
\]

(23)

which is valid for \(0.01 \leq \phi \leq 0.04\) and \(300K \leq T_{env} \leq 325K\).

We choose \(T_{env} = 300K\) in the present study, for the expression for the thermal conductivity, the thermal diffusivity of nanofluids is then given by

\[
a_{nf} = \frac{k_{nf}}{(\rho c_p)_{nf}}.
\]

(24)

The effective viscosity of nanofluids is given by

\[
A = \mu_{nf} = \mu_s + \mu_B.
\]

(25)
where \( \mu_s \) is evaluated by Brinkman model
\[
\mu_s = \mu_{nf}(1 - \varphi)^{-2.5}
\] (26)
and \( \mu_B \) is expressed as
\[
\mu_B = 5 \times 10^4 \gamma_f \phi P_{nf} \left( \frac{\kappa T_{enf}}{\rho_{nf} d_f^4} \right) .
\] (27)

The thermophysical properties, for pure water, copper are listed in Table 1.

Entropy generation can be defined as follows (Pakdemirli and Yilbas 2006, Souidi et al. 2009)

\[
S_G = \frac{k_{nf}}{T_0} \left( \frac{\partial \theta}{\partial r} \right)^2 + \frac{\mu_{nf}}{T_0} \left( \frac{\partial \theta}{\partial z} \right)^2 + \frac{\alpha_{nf}}{T_0} \left( \frac{\partial \theta}{\partial r} \right) \left( \frac{\partial \theta}{\partial z} \right) + \frac{\nu_{nf}}{T_0} \left( \frac{\partial \theta}{\partial r} \right)^2 + \frac{\nu_{nf}}{T_0} \left( \frac{\partial \theta}{\partial z} \right)^2 \right),
\] (28)

Dimensionless form of the Entropy Generation with the help of Eq. (10) due to fluid friction and magnetic field is given as:

\[
N_s = \frac{S_G}{S_{G0}} = \frac{k_{nf}}{k_f} \left( \frac{\partial \theta}{\partial r} \right)^2 + \frac{\mu_{nf}}{\mu_f} \left( \frac{\partial \theta}{\partial z} \right)^2 + \frac{\alpha_{nf}}{\alpha_f} \left( \frac{\partial \theta}{\partial r} \right) \left( \frac{\partial \theta}{\partial z} \right) + \frac{\nu_{nf}}{\nu_f} \left( \frac{\partial \theta}{\partial r} \right)^2 + \frac{\nu_{nf}}{\nu_f} \left( \frac{\partial \theta}{\partial z} \right)^2 ,
\] (29)

The dimensionless form of \( S_G \) is known as entropy generation number \( N_s \), which is the ratio of actual entropy generation rate to the characteristic entropy transfer rate \( S_{G0} \), which is defined as follows

\[
S_{G0} = \frac{k_f}{T_0} \left( \frac{\partial \theta}{\partial r} \right)^2, \quad B_r = \frac{\mu_f}{k_f} \left( \frac{\partial \theta}{\partial r} \right) , \quad \Lambda = \frac{T_0}{T_f - T_0}.
\] (30)

Equation (28) consists of two parts. The first part is the entropy generation due to finite temperature difference (\( N_{\text{cond}} \)) and the second part is the entropy generation due to viscous effects (\( N_{\text{visc}} \)). The Bejan number is defined as (Nada, 2006)

\[
B_e = \frac{N_{\text{cond}}}{N_{\text{cond}} + N_{\text{visc}}}. \] (31)

3. SOLUTION OF THE PROBLEM

The exact solutions of the above equations are found as follows
\[
\left( \frac{\partial \theta}{\partial r} \right) = C_1 J_0 \left( \frac{\mu_f}{\mu_f} \right) + C_2 Y_0 \left( \frac{\mu_f}{\mu_f} \right) ,
\] (32)

where
\[
C_1 = \frac{d p}{d z} \left( \frac{\mu_f}{\mu_f} \right) Y_0 \left( \frac{\mu_f}{\mu_f} \right) ,
\] (33)

The corresponding stream function can be defined as
\[
u = \frac{1}{r} \frac{\partial w}{\partial \theta}, \quad w = \frac{1}{r} \frac{\partial \theta}{\partial r},
\] (37)

The pressure rise \( \Delta p \) is defined as follows
\[
\Delta p = \int \frac{d p}{d z} dz, \] (38)

where the \( \frac{d p}{d z} \) is defined in Eq.

The flow rate \( F \) in non dimensionalized form is given as
\[
F = 2Q \Omega - \frac{\Omega^2}{2} - 1.
\] (39)

\( C_3, C_4 \) are constants and \( K[1], K[2] \) evaluated using Mathematica 9.

4. RESULTS AND DISCUSSION

In this section we study the behavior of the solutions in the form of graphs, for several values: Hartmann number \( M \), and volume flow rate \( Q \) has been carried out for both pure water and
copper water. The variation of $Q$ and $M$ on pressure gradient is shown in Fig. 2, it shows that pressure gradient is decreasing on an increase in $M$ for both types of fluid it is also observed that pressure gradient is least in case of copper water where as the effect of $M$ is relatively larger in case of pure water.

![Fig. 2. Variation of pressure gradient $dp/dz$ for different flow parameters.](image)

In order to analyze pumping characteristics, numerical integration is performed and results are shown the variation of pressure rise per wavelength $\Delta p$ against time average flux $Q$ in Fig. 3. Fig.3 shows the effect of $M$ on pressure rise, it is observed that pressure rise increases by increase in $M$ in the region $\Delta p > 0, Q > 0$ while the opposite behavior is observed in the region $\Delta p < 0, Q < 0$. Figs. 4(a)–4(c) to understand the variation of temperature distribution for different values of $\varphi$, $M$ and $Br$. Fig. 3(a) shows that $\theta$ increases as we increase $\varphi$ for copper water fluid. When we observe Figs. 4(b) and 4(c), the same trend is observed for Hartmann number $M$ and Brinkman number $Br$ respectively, we have observed that by increasing $M$ and $Br$, temperature is increasing.

![Fig. 3. Variation of pressure rise $\Delta p$ for different flow parameters.](image)

![Fig. 4. Variation of temperature profile $\theta$ for different flow parameters.](image)

We have plotted Fig. 5 to illustrate the effects of pertinent parameters on velocity profile $w$. It is observed from Fig. 5(a) that velocity profile increases with increase in the value of $\varphi$ near the wall of tube $r_2$. However, opposite behavior is shown near the wall $r_1$, i.e. along with the sinusoidal wall, volume friction increases the velocity of fluid. We have presented the Figs.5 (b) to obtain the variation of velocity profile $u$ for varying the magnitude of the parameters $M$ for both types of fluid. It depicts that velocity is decreasing with increase of $M$ along the wall $r_2$, but opposite behavior is shown along the rigid tube's wall $r_1$. Figs 5(c) show the variations of average flow rate $Q$ on velocity profile it depicts that velocity increases with an increase in $Q$ it is also observed that there is the least effect of $Q$ on velocity in the case of copper water as compare to pure water.
Fig. 5. Variation of velocity profile $u$ with for different flow parameters.

We have presented the Fig. 6 to obtain the variation of entropy generation number $N_s$ for varying the magnitude of the parameters $\varphi$, $M$, $Br$, and $A$. From Fig. 6(a) it depicts that $N_s$ is increasing with increase nano particle volume friction parameter $\varphi$. Figs 6 (b) and 6 (c) shows that $N_s$ is directly proportional to the $M$ and $Br$ throughout the channel but considerable impact is not observed along the walls for both types of fluid in case of Hartmann number and the impact of copper water is observed more than pure water. Nevertheless Fig 6 (d) shows the higher value of $A$ displays least entropy.

Figs. 7(a) – 7(d) are prepared to analyze the Bejan number with respect to change in different physical constraints involved. Fig. 8(a) depicts that with the increase in $\varphi$, there is a increase in Bejan number. Fig.7 (b) shows the variation of Bejan number for different values of $M$. we see that near the wall $r_2$ Bejan number is not influenced to considerable degree while near the wall $r_1$ Bejan number is decreasing by increase in the values of $M$. Fig.7 (c) shows that there is an opposite behavior for $Br$ as we see for $M$. We have observed in Fig. 8 (d) that $Be$ is increasing by increase in $A$ but the impact on copper water is greater than the impact of pure water.

Another important phenomenon in peristaltic transport is trapping. The formation of an internally circulating bolus of fluid by closed streamlines is called trapping and is pushed a head along with the peristaltic wave. The physical phenomena may be responsible for thrombus formation in blood and the movement of food bolus in gastrointestinal tract. Fig. 8 show contour maps for the streamlines with four values of $\varphi$ ($\varphi = 0.01, \varphi = 0.02, \varphi = 0.03, \varphi = 0.04$) copper water. It is noticed that bolus becomes Smaller when we give greater values of $\varphi$.

Figs. 9 and 10 show the the effect of Hartmann number $M$ on streamlines for pure water and copper water respectively it is shown that bolus becomes large as larger values of $M$. Figs. 11 and 12 show the effect of flow rate $Q$ on streamlines for pure water and copper water respectively it is shown that bolus becomes large as larger values of $Q$.

5. CONCLUSION

Interaction of Copper nanoparticles for the peristaltic flow in endoscope with the magnetic field is discussed, key points are observed as follows:

1. It is observed that effect of nano particle friction on pressure gradient considerable impact i.e, more the volume friction, lesser the pressure gradient.

2. It is observed that temperature increases as we increase Brinkman number and Hartmann number for both types of fluid.

3. velocity is decreasing with increase of $M$ along the sinusoidal wall , but opposite behavior is shown along the rigid tube's wall.

4. It is observed that Entropy generation number are increasing with increase of Brinkman number.

5. It is observed near the sinusoidal wall Bejan number is not influenced to considerable degree while near the rigid wall Bejan number is decreasing by increase in the values of Hartmann number.

6. It is noticed that size, of bolus becomes smaller when we give greater values of nano particle volume friction for copper water.
